ECE 454 Computer Systems Programming

Compiler Optimizations

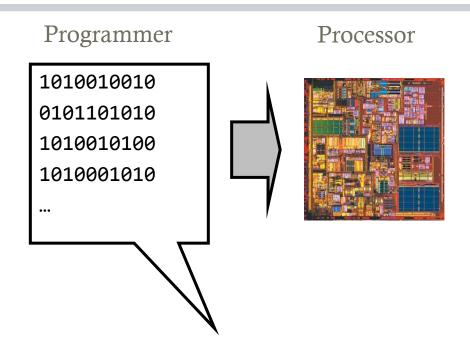

Ashvin Goel, Ding Yuan ECE Dept, University of Toronto

Content

- History and overview of compilers
- Basic compiler optimizations
- Program optimizations
- Advanced optimizations
 - Parallel unrolling
 - Profile-directed feedback

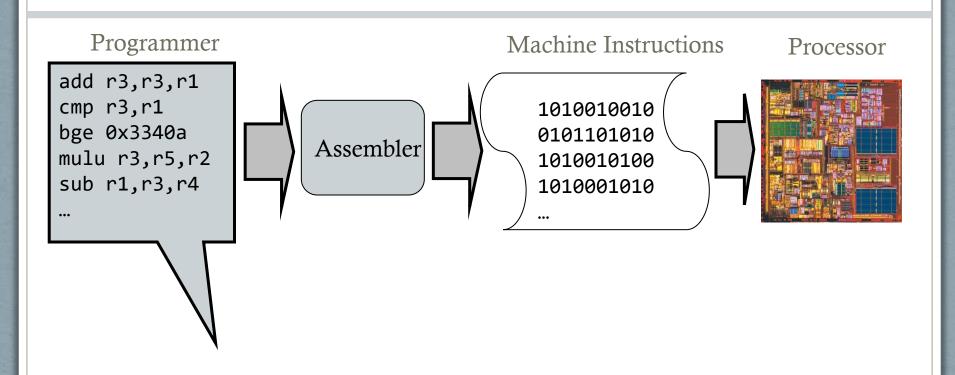

A Brief History of Compilation

In the Beginning...

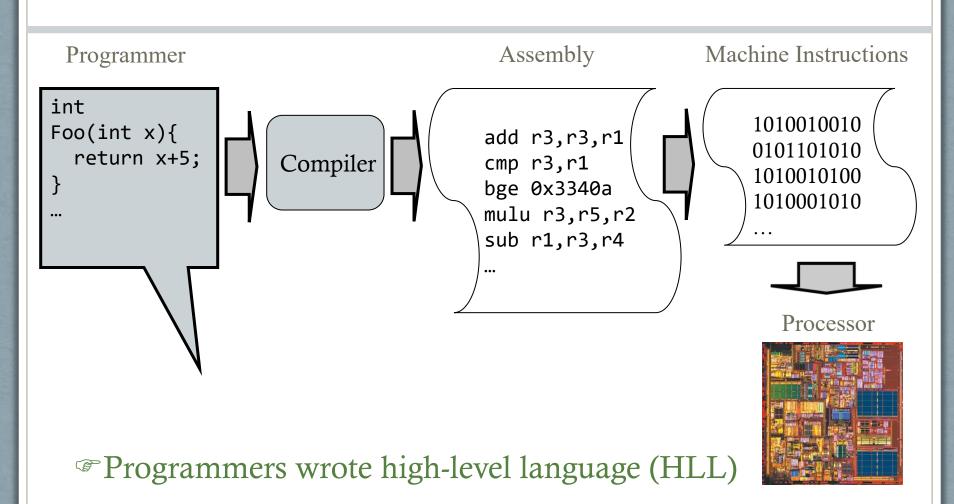

Programmers wrote machine instructions

Then Came the Assembler

Programmers wrote human-readable assembly

Then Came the Compiler

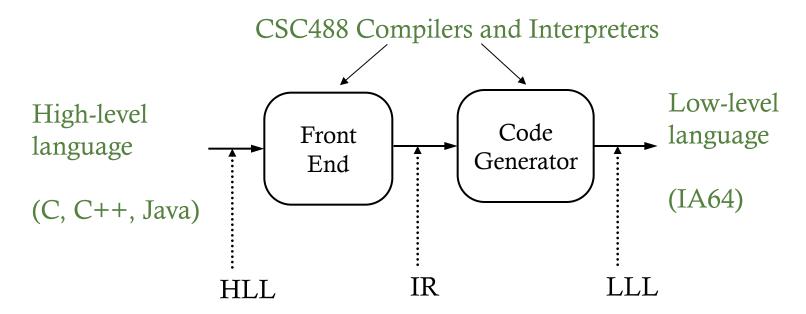

Overview of Compilers

Goals of a Compiler

- Correct program executes correctly
- Provide support for debugging incorrect programs
- Program executes fast
- Compilation is fast?
- Small code size?
- More energy efficient program?

Inside a Basic Compiler

Intermediate Representation (similar to assembly)

Control Flow Graph:

(how a compiler sees your program)

Example IR:

add ...

L1: add ...

add ...

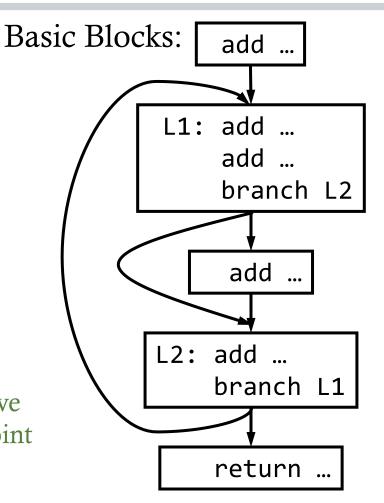

branch L2

add ...

L2: add ...

branch L1 return ...

Basic Block: a group of consecutive instructions with a single entry point and a single exit point

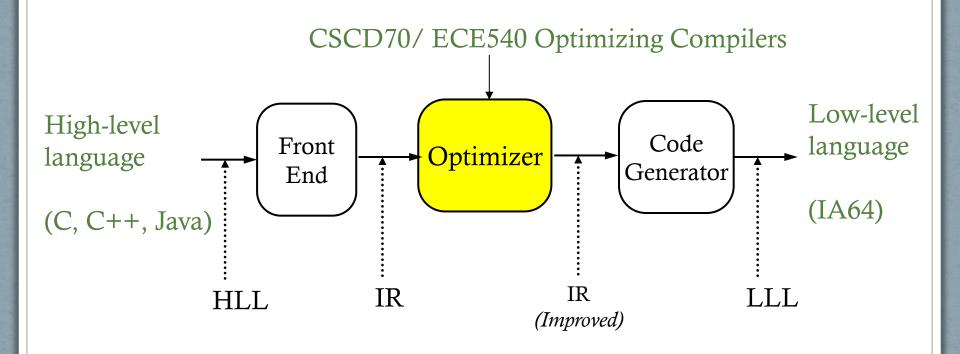

Data Flow Analysis

- Many compiler optimizations (discussed later) use a technique called data flow analysis
- Basic idea
 - Analyse and summarize the effects of instructions in a basic block
 - Use CFG to propagate these effects to succeeding basic blocks
- E.g., reaching definition data flow analysis
 - Calculates for each program point 1: if b==4 then the set of definitions (program points) that may potentially reach this program point

```
// BB1
                     // BB2
      a = 5;
3:else
      a = 3;
                     // BB3
5:endif
6:if a < 4 then ... // BB4
```

Inside an Optimizing Compiler

Performance Optimization: 3 Requirements

- Preserve correctness
 - The speed of an incorrect program is irrelevant
- Improve performance of average case
 - Optimized program may be worse than original if unlucky
- Be "worth the effort"
 - Is this example worth it?
 - 1 person-year of work to implement compiler optimization
 - 2x increase in compilation time
 - 0.1% improvement in speed

How do Optimizations Improve Performance?

Recall

```
Execution_time = num_instructions * CPI * time/cycle
```

- Fewer instructions
 - Use optimized sequence of instructions
 - Use new instructions
- Fewer cycles per instruction
 - Schedule instructions to avoid hazards
 - Improve cache/memory behavior
 - E.g., prefetching, code and data locality

Role of Optimizing Compilers

- Provide efficient mapping of program to machine instructions
 - Eliminate minor inefficiencies
 - Register allocation
 - Instruction selection
 - Instruction scheduling

- Don't (usually) improve asymptotic efficiency
 - Up to programmer to select best overall algorithm
 - Big-O savings are (often) more important than constant factors
 - But constant factors also matter

Limitations of Optimizing Compilers

- Operate under fundamental constraints
 - Must not cause any change in program behavior under any possible condition
- Most analysis is performed only within procedures
 - Inter-procedural analysis is too expensive in most cases
- Most analysis is based only on static information
 - Compiler has difficulty anticipating run-time inputs
- When in doubt, the compiler must always be conservative

Role of the Programmer

- How should I write my programs, given that I have a good, optimizing compiler?
- Don't: smash code into oblivion
 - Hard to read, maintain, assure correctness

Role of the Programmer

- How should I write my programs, given that I have a good, optimizing compiler?
- Do:
 - Select best algorithm
 - Write code that's readable and maintainable
 - Procedures, recursion
 - Even though these may slow down code
 - Focus on inner loops
 - Do detailed optimizations where code will be executed repeatedly
 - Will get most performance gain here
 - Eliminate optimization blockers
 - Allows compiler to do its job!

Basic Compiler Optimizations

Compiler Optimizations

- Machine independent (apply equally well to most CPUs)
 - Constant propagation
 - Constant folding
 - Copy propagation
 - Common subexpression elimination
 - Dead code elimination
 - Loop invariant code motion
 - Function inlining

Compiler Optimizations

- Machine dependent (apply differently to different CPUs)
 - Instruction selection and scheduling
 - Loop unrolling
 - Parallel unrolling
- Possible to do all these optimizations manually, but much better if compiler does them
 - Many optimizations make code less readable/maintainable

Constant Propagation (CP)

• Replace variables with constants when possible

```
a = 5;
b = 3;
:
n = 5 + 3

n = a + b;
for (i = 0; i < n; ++i) {
:
}</pre>
```

Constant Folding (CF)

• Evaluate expressions containing constants

- Can lead to further optimization
 - E.g., another round of constant propagation

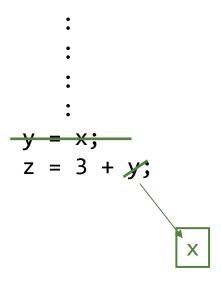

Common Sub-Expression Elimination (CSE)

• Try to only compute a given expression once

Need to ensure the variables have not been modified

Copy Propagation

• Replace target of assignment with corresponding value

 Often used after common sub-expression elimination and other optimizations

Dead Code Elimination (DCE)

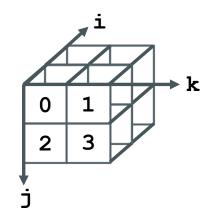

• Compiler can determine if certain code will never execute

- Compiler will remove that code
 - You don't have to worry about such code impacting performance
 - Makes it easier to have readable/debugable programs

- Loop invariant: value does not change across iterations
- LICM: moves invariant code out of the loop
- Leads to significant performance win

Consider this triply nested loop

```
for (i=0; i < I; ++i) {
  for (j=0; j < J; ++j) {
    for (k=0; k < K; ++k) {
      a[i][j][k] = i*j*k;
    }
}</pre>
```

• In C, a multi-dimensional array is stored in row-major order

a[0][0][0] a[0][0][1] ... a[0][0][K-1] a[0][1][0] ... a[I-1][J-1][0] .. a[I-1][J-1][K-1]

```
char a[I][J][K]; addr of a[i][j][k] = (addr of a) + (i x J x K) + (j x K) + (k)
```

```
addr of a[i][j][k] = (addr of a) + (i x J x K) + (j x K) + (k)

for (i=0; i < I; ++i) {
  for (j=0; j < J; ++j) {
    for (k=0; k < K; ++k) {
      a[i][j][k] = i*j*k;
    }
  }
}
</pre>

for (i = 0; i < I; ++i) {
    t1 = a + i * J * K; // t1=a[i];
  for (j = 0; j < J; ++j) {
    t2 = t1 + j * K; // t2=t1[j];
  for (k = 0; k < K; ++k) {
    t2[k] = i * j * k;
    }
}
}
</pre>
```

```
addr of a[i][j][k] = (addr of a) + (i x J x K) + (j x K) + (k)

for (i = 0; i < I; ++i) {
  for (j = 0; j < J; ++j) {
    for (k = 0; k < K; ++k) {
      a[i][j][k] = i*j*k;
    }
}

}

}

addr of a[i][j][k] = (addr of a) + (i x J x K) + (j x K) + (k)

for (i = 0; i < I; ++i) {
    t1 = a + i * J * K; // t1 = a[i];
    for (j = 0; j < J; ++j) {
      t2 = t1 + j * K; // t2 = t1[j];
    tmp = i * j;
    for (k = 0; k < K; ++k) {
      t2[k] = tmp * k;
    }
}
</pre>
```

- When I=J=K=100, inner loop will execute 1,000,000 times
 - Many of the computations in the inner loop are moved out
 - Improves performance dramatically

Function Inlining

• A function call site is replaced with the body of the function

```
main(){
foo(int z){
  int m = 5;
  return z + m;
                         int foo_z = x;
                          int foo_m = 5;
main(){
                          int foo_return = foo_z + foo_m;
                         x = foo_return;
  x = foo(x);
                                                  main(){
                                                    x = x + 5;
```

Function Inlining

- Performance
 - Eliminates call/return overhead
 - Can expose potential optimizations
 - Can be hard on instruction-cache if many copies made
 - Code size can increase if large procedure body and many calls
- As a programmer
 - A good compiler should inline for best performance
 - Feel free to use procedure calls to make your code readable!

Loop Unrolling

```
j = 0;
while (j < 100){
    a[j] = b[j+1];
    j += 1;
}</pre>
```

```
j = 0;
while (j < 99){
    a[j] = b[j+1];
    a[j+1] = b[j+2];
    j += 2;
}</pre>
```

- Reduces loop overhead, why?
 - Fewer adds to update j
 - Fewer loop condition tests
 - Reduces branch penalties
- Enables more aggressive instruction scheduling
 - I.e., more instructions in loop basic block for scheduler to move around

Summary: gcc Optimization Levels

- -g: Include debug information, no optimization
- -O0: Default, no optimization
- -O1: Do optimizations that don't take too long
 - CP, CF, CSE, DCE, LICM, inline functions called once
- -O2: Take longer optimizing, more aggressive scheduling
 - E.g., inline small functions
- -O3: Make space/speed trade-offs
 - Can increase code size, loop unrolling, more inlining
- -Os: Optimize program size
